# Appendix A: Example dsm analysis

David L. Miller, M. Louise Burt, Eric A. Rexstad and Len Thomas

### Preamble

This is a knitr document. The source for it contains everything you need to reproduce the analysis given here (aside from the data). The most recent version of this document can always be found at github.com/dill/mexico-data.

The data (which are included in the dsm package) consist of observations of dolphins in the Gulf of Mexico. The analysis is based on a dataset which is shipped with Distance 6.0. For convenience the data are bundled in an R friendly format, although all of the code necessary for creating the data from the Distance project files is available at the above URL.

The intention here is to highlight the features of the dsm package, rather than perform a full analysis of the data. For that reason, some important steps are not fully explored. Some familiarity with density surface modelling is assumed.

Before we start, we load the dsm package and set some options:

### library(dsm)

```
## Loading required package: mgcv

## This is mgcv 1.7-22. For overview type 'help("mgcv-package")'.

## Loading required package: mrds

## Loading required package: optimx

## Loading required package: numDeriv

## Loading required package: Rsolnp

## Loading required package: truncnorm

## This is mrds 2.0.9 Built: R 2.15.2; ; 2012-12-10 10:15:50 UTC; unix
```

```
## Loading required package: ggplot2
## Loading required package: Distance
## This is dsm 2.0 Built: R 2.15.2; ; 2013-01-09 17:42:42 UTC; unix
# plotting options
gg.opts <- theme(panel.grid.major = element_blank(), panel.grid.minor = element_blank(),
    panel.background = element_blank())
# make the results reproducable
set.seed(11123)</pre>
```

#### The data

### Observation and segment data

All of the data for this analysis has been nicely pre-formatted and is shipped with dsm. Loading up that data, we can see that we have four data frames, the first few lines of each are shown:

```
data(mexdolphins)
attach(mexdolphins)

distdata holds the distance sampling data which will be used to fit the detection function. segdata holds the segment data: the transects have already been "chopped" into segments. obsdata holds the observations which have already been aggregated to the segments and preddata holds the prediction grid (which includes all the covariates that we need).

Typically it will be necessary to pre-allocate the observations to segments (as well as define the segment length) using a tool such as ArcGIS before starting an analysis using dsm.

The below figure shows the survey area with the transect lines overlaid (using data from segdata).

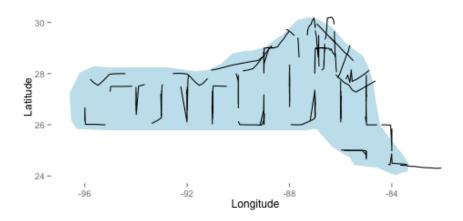

Figure 1: The survey area with transect lines.

## Converting units

It is important to ensure that the measurements to be used in the analysis are in compatible units, otherwise the resulting estimates will be incorrect or hard to interpret. Having all of our measurements in SI units from the outset removes the need for conversion later, making life much easier. All of the data is already in the appropriate units (Northings and Eastings: kilometres from ~-88.32 longitude, ~27.02 latitude, which is the centroid of the study region, multiplyied up by 1000 to get the result in metres for consistency).

It is also important to note that the area of the prediction cells must be included for prediction to work. Our data includes the width and height of each prediction

cell and we calculate the areas as needed. See below.

We give an example of converting the survey area here to show that this is a simple process:

The function latlong2km makes this conversion simple (thanks to Simon N. Wood for providing code). The other data frames have already had their measurements appropriately converted. Note that by convention the directions are named x and y.

Using latitude and longitude when performing spatial smoothing can be problematic when certain smoother bases are used. In particular when bivariate isotropic bases are used the non-isotropic nature of latitude and longitude is inconsistent (moving one degree in one direction is not the same as moving one degree in the other).

# Exploratory data analysis

### Distance data

The top panels of the below figure show histograms of observed distances and group size and the bottom panels show the relationship between observed distance and observed group size, and the relationship between observed distance and Beaufort sea state. The plots show that there is some relationship between size and observed distance to be explored since as one would expect, fewer smaller groups seem to be seen at larger distances.

```
# save graphics options
o <- par("mfrow")
par(mfrow = c(2, 2))

# histograms
hist(distdata$distance, main = "", xlab = "Distance (m)")
hist(distdata$size, main = "", xlab = "Group size")</pre>
```

### Spatial data

Looking separately at the at the spatial data without thinking about the distances, we can see the distribution of group size in space in the below figure. Circle size indicates the size of the group in the observation. There are rather large areas with no observations, which might cause our variance estimates to be rather large.

We will use depth later as an explanatory covariate in our spatial model. The next plot shows the raw depth data.

```
p <- ggplot(preddata)
p <- p + gg.opts</pre>
```

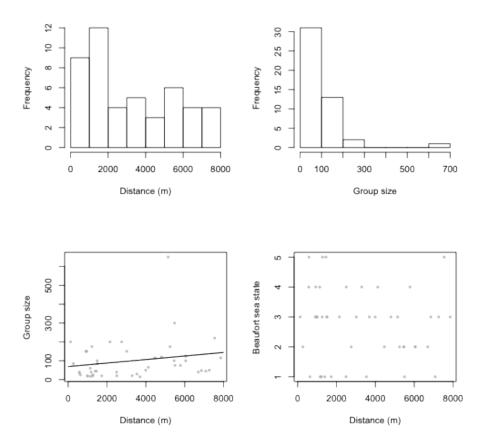

Figure 2: Exploratory plot of the distance sampling data. Top row, left to right: histograms of distance and group size; bottom row: plot of distance against group size and plot of distances against Beaufort sea state.

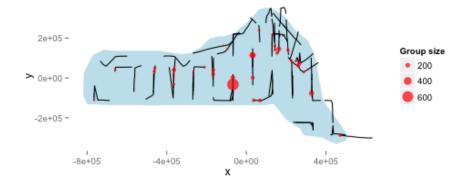

Figure 3: The survey area. Point size is proportional to the group size for each observation.

```
p <- p + coord_equal()
p <- p + labs(fill = "Depth", x = "x", y = "y")
p <- p + geom_tile(aes(x = x, y = y, fill = depth, width = width, height = height))
print(p)</pre>
```

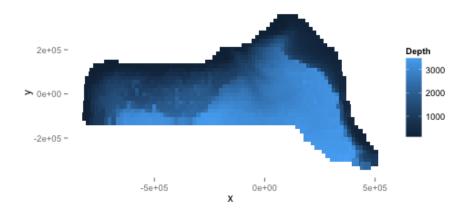

Figure 4: Plot of depth values over the survey area.

Combining the above two plots yields:

This plot shows that we don't seem to have many observations in the very shallow aeas near the shore. This should make us skeptical of predictions in those areas.

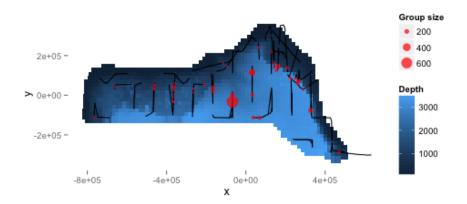

Figure 5: Plot of depth values over the survey area with transects and observations overlaid.

model.

We use the ds function in Distance to fit the detection function. First, loading the Distance library:

We can then fit a detection function with hazard-rate key with no adjustment

```
hr.model <- ds(distdata, max(distdata$distance), key = "hr", adjustment = NULL)
## Fitting hazard-rate key function

Estimate

#### **Detection function plot**

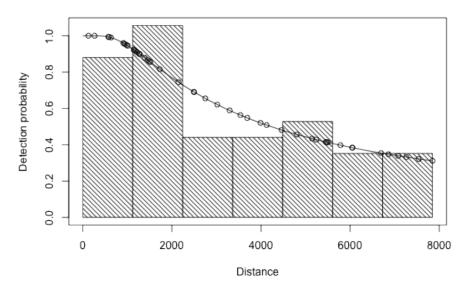

Figure 6: Plot of the fitted detection function.

# Fitting a DSM

Before fitting a dsm model, the data must be segmented; this consists of chopping up the transects and attributing counts to each of the segments. As mentioned above, these data have already been segmented.

# A simple model

We begin with a very simple model. We assume that the number of individuals in each segment are quasi-Poisson distributed and that they are a smooth function of their spatial coordinates (note that the formula is exactly as one would specify to gam in mgcv). The abundance of groups rather than individuals can be estimated by setting group=TRUE (though we ignore this here).

Running the model:

```
mod1 <- dsm(N ~ s(x, y), hr.model$ddf, segdata, obsdata)
summary(mod1)
##

We can then make the predictions over the the grid and calculate abundance.
First we must create the offset (the area of each grid cell, which is 444km<sup>2</sup>).
off.set <- 444 * 1000 * 1000
mod1.pred <- predict(mod1, preddata, off.set)</pre>
Below is a map of the predicted abundance. Before plotting, we bind on the
predicitons to the data used to create them:
pp <- cbind(preddata, mod1.pred)</pre>
Then plotting:
p <- ggplot(pp) + gg.opts</pre>
p <- p + geom_tile(aes(x = x, y = y, fill = mod1.pred, width = width, height = height))
p <- p + coord_equal()</pre>
p <- p + scale_fill_gradientn(colours = heat_hcl(1000))</pre>
## Error: could not find function "heat_hcl"
p \leftarrow p + geom_path(aes(x = x, y = y), data = survey.area)
p <- p + labs(fill = "Abundance")</pre>
```

print(p)

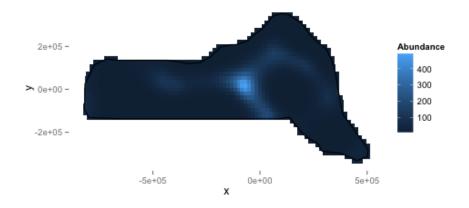

Figure 7: Predicted density surface for mod1.

We can calculate abundance over the survey area by simply summing these predictions:

```
sum(mod1.pred)
## [1] 47034
```

We can also look at diagnostic plots for the model.

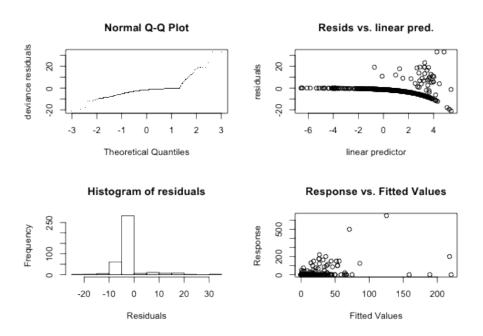

Figure 8: Diagnostic plots for mod1.

These show that there is some deviation in the Q-Q plot. The "line" of points in the plot of the residuals vs. linear predictor plot corresponds to the zeros in the data.

We can use the approach of Williams et al (2011), which accounts for uncertainty in detection function estimation.

```
preddata.varprop <- split(preddata, 1:nrow(preddata))
offset.varprop <- as.list(rep(off.set, nrow(preddata)))
mod1.varprop <- dsm.var.prop(mod1, pred.data = preddata.varprop, off.set = offset.varprop)</pre>
```

Calling summary will give some information about uncertainty estimation:

```
summary(mod1.varprop)
```

## Summary of uncertainty in a density surface model calculated
## by variance propagation.

```
##

We can also make a plot of the CVs:
plot(mod1.varprop, xlab = "Easting", ylab = "Northing")
```

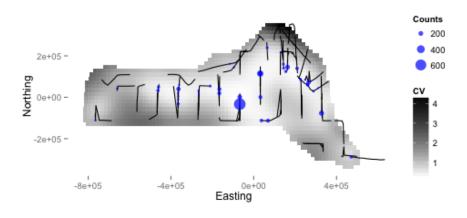

Figure 9: Plot of the coefficient of variation for the study area.

#### Adding another covariate to the spatial model

The data set also contains a depth covariate (which we plotted above). We can include in the model very simply:

```
mod2 \leftarrow dsm(N \sim s(x, y, k = 10) + s(depth, k = 20), hr.model, segdata, obsdata,
    select = TRUE)
summary(mod2)
##

```

By setting the k parameter we specify the largest complexity for that smooth term in the model; as long as this is high enough (i.e. the number in the edf column is not too close to that in the Ref.df column, we can be sure that there is enough flexibility. However, it may sometimes be necessary to set k to be lower than this to limit the influence of (for example) spatial smoothers in the model.

Setting select=TRUE here imposes extra shrinkage terms on each smooth in the model (allowing smooth terms to be removed from the model during fitting, see ?gam for more information). Although this is not particularly useful here, this can be a good way (along with looking at p-values) to perform term selection.

Again we can plot the predictions from this model:

```
mod2.pred <- predict(mod2, preddata, off.set)
pp <- cbind(preddata, mod2.pred)
p <- ggplot(pp) + gg.opts
p <- p + labs(fill = "Abundance")
p <- p + geom_tile(aes(x = x, y = y, fill = mod2.pred, width = width, height = height))
p <- p + coord_equal()
p <- p + scale_fill_gradientn(colours = heat_hcl(20))

## Error: could not find function "heat_hcl"

p <- p + geom_path(aes(x = x, y = y), data = survey.area)
print(p)</pre>
```

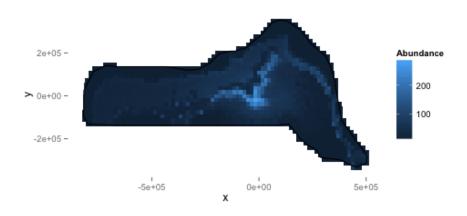

Figure 10: Predicted density surface for mod2.

We can also look at the relationship between depth and abundance:

```
plot(mod2, select = 2)
```

Omitting the argument select gives plots of all the smooth terms, one at a time.

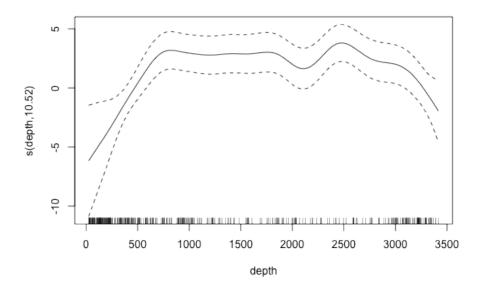

Figure 11: Plot of the smooth of depth in mod2.

## A more complicated model

### Tweedie

Response distributions other than the quasi-Poisson can be used, for example the Tweedie distribution. If the Tweedie is used, then the p parameter must be specified. Mark Bravington (via personal communication) suggests the use of p=1.2 for marine mammal work. The choice of p is only sensitive to the first decimal place, so a quick search can be performed by simply comparing the score of the resulting models.

```
mod3 <- dsm(N ~ s(x, y), hr.model, segdata, obsdata, family = Tweedie(p = 1.2))
summary(mod3)

##

Note that we have to fully specify the family just as in mgcv.
As well as looking at the GCV/UBRE/REML score of the model to assess the
value of p we can also look at a plot of the square root of the absolute value of
the residuals versus the fitted values gives the following plot:
plot(sqrt(abs(residuals(mod3))), predict(mod3), xlab = "Square root of the absolute value of
    ylab = "Fitted values")
where as setting p=1.7:
mod3 \leftarrow dsm(N \sim s(x, y), hr.model, segdata, obsdata, family = Tweedie(p = 1.7))
summary(mod3)
##

##
           edf Ref.df
                         F p-value
```

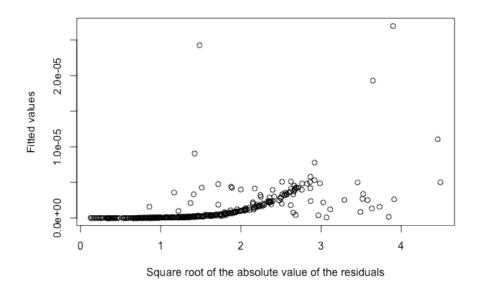

Figure 12: Plot of absolute value of the residuals versus the fitted values for the Tweedie model when p=1.2

we obtain the following plot, which appears to be much flatter:

```
plot(sqrt(abs(residuals(mod3))), predict(mod3), xlab = "Square root of the absolute value or
    ylab = "Fitted values")
```

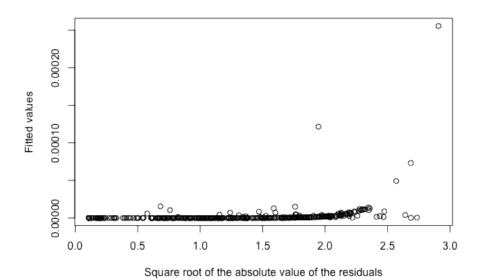

Figure 13: Plot of absolute value of the residuals versus the fitted values for the Tweedie model when p=1.7, note that this plot is much flatter than the previous plot.

Note also the improvement in GCV score.

In general, a "good" value can be found by simply plotting the above along with the GCV score for the model for values of p between 1.1 and 1.9 and looking for the best GCV and "flattest" plot.

# Soap film smoothing

To account for a complex region (e.g. a region that includes peninsulae) we can use the soap film smoother. This is provided by the soap film smoother (see references, below).

In order to use a soap film smoother for the spatial part of the model we must create a set of knots for the smoother to use. This is easily done using the make\_soap\_grid() function in dsm:

```
soap.knots <- make.soapgrid(survey.area, c(11, 6))
## Warning: the condition has length > 1 and only the first element will be
## used
# knot 11 is not outside but is too close according to soap...
soap.knots <- soap.knots[-11, ]</pre>
```

where the second argument specifies the size of the grid that will be used to create the knots (knots in the grid outside of survey.area are removed).

As we saw in the exploratory analysis, some of the transect lines are outside of the survey area. These will cause the soap film smoother to fail, so we remove them:

```
x <- segdata$x
y <- segdata$y
onoff <- inSide(x = x, y = y, bnd = survey.area)

## Warning: the condition has length > 1 and only the first element will be
## used

rm(x, y)
segdata <- segdata[onoff, ]

We can run a model with both the depth covariate along with a spatial (soap
film) smooth:

mod4 <- dsm(N ~ s(x, y, bs = "so", k = 10, xt = list(bnd = list(survey.area))) +
        s(depth), hr.model, segdata, obsdata, knots = soap.knots)

## Loading required package: Matrix

```

Not that the k argument now refers to the complexity of the boundary smooth in the soap film and the complexity of the film is controlled by the knots given in the xt argument.

Comparing predictions from the model that included a smooth of depth, we can see that the soap film has prevented some of the extreme values (especially in the lower right corner of the survey area).

```
mod4.pred <- predict(mod4, preddata, off.set)
pp <- cbind(preddata, mod4.pred)

p <- ggplot(pp) + gg.opts
p <- p + geom_tile(aes(x = x, y = y, fill = mod4.pred, width = width, height = height))
p <- p + coord_equal()
p <- p + scale_fill_gradientn(colours = heat_hcl(20))</pre>
```

```
## Error: could not find function "heat_hcl"

p <- p + geom_path(aes(x = x, y = y), data = survey.area)
p <- p + labs(fill = "Abundance")
print(p)</pre>
```

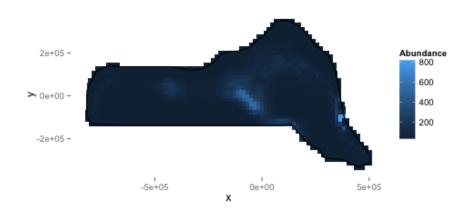

Figure 14: Predicted density surface for mod4.

# Adding covariates to the detection function

It is common to include covariates in the detection function (so-called Multiple Covariate Distance Sampling or MCDS). In this dataset there is two covariates which are collected on each individual: Beaufort sea state and size. For brevity we fit only a hazard-rate detection functions with the sea state included as a factor covariate as follows:

```
hr.beau.model <- ds(distdata, max(distdata$distance), formula = ~as.factor(beaufort),
    key = "hr", adjustment = NULL)
summary(hr.beau.model)</pre>
```

##

```
## Summary for distance analysis
## Number of observations : 47

                                            CV
## Average p
                         0.5421 0.1751 0.3229
## N in covered region 86.6957 29.4133 0.3393
```

Note that we opt to not use adjustments with the covariate model since we cannot ensure that the detection function will remain monotonic if both covariates and adjustment terms are used.

We fit the model as above, simply replacing the detection function model object and changing the response to be Nhat so the abundances are estimated per segment:

```
mod5 <- dsm(Nhat ~ s(x, y), hr.beau.model, segdata, obsdata)
summary(mod5)

##
## Family: quasipoisson
## Link function: log
##
## Formula:
## Nhat ~ s(x, y) + offset(off.set)
## <environment: 0x123e7fd58>
##
## Parametric coefficients:
## Estimate Std. Error t value Pr(>|t|)
## (Intercept) -17.919  0.274  -65.5  <2e-16 ***</pre>
```

```
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
##
## Approximate significance of smooth terms:
## edf Ref.df F p-value

##
## R-sq.(adj) = 0.119 Deviance explained = 40.7%
## GCV score = 81.573 Scale est. = 71.124 n = 365
```

Note that for models where there are covariates at the individual level we cannot calculate the variance via the variance propagation method of Williams et al (2011), but rather must resort to the moving block bootstrap. Other than this, all of the above models can be fitted.

A plot of predicitons from the covariate model:

```
mod5.pred <- predict(mod5, preddata, off.set)
pp <- cbind(preddata, mod5.pred)

p <- ggplot(pp) + gg.opts
p <- p + geom_tile(aes(x = x, y = y, fill = mod5.pred, width = width, height = height))
p <- p + coord_equal()
p <- p + scale_fill_gradientn(colours = heat_hcl(20))

## Error: could not find function "heat_hcl"

p <- p + geom_path(aes(x = x, y = y), data = survey.area)
p <- p + labs(fill = "Abundance")
print(p)</pre>
```

### Conclusions

This document has hopefully shown that the dsm package is a versatile and relatively easy-to-use package for the analysis of spatial distance sampling data. Note that there are many possible models that can be fitted using dsm and that the aim here was to show just a few of the options. Results from the models can be rather different, so care must be taken in performing model selection and discrimination.

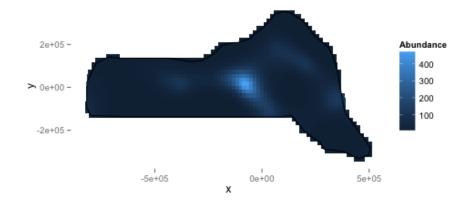

Figure 15: Predicted density surface for mod5.

# Notes

- Distance is available at <a href="http://github.com/dill/Distance">http://github.com/dill/Distance</a> as well as on CRAN.
- dsm is available (along with some documentation and hints) at http://github.com/dill/dsm, as well as on CRAN.
